ABSTRACT

Introduction: The world health organization estimates that anaemia largely caused by iron deficiency, affecting between 500 million and two billion people worldwide. Considering the age prevalence of iron deficiency anaemia and febrile convulsion which are the same, the role of iron in the metabolism of neurotransmitter and some enzymes and since fever can exacerbate symptoms that result from anaemia, a relationship between iron deficiency anaemia and febrile convulsions is probable. Some studies have suggested iron deficiency as a predisposing factor for febrile seizures. Material and methods: A case control study was done to evaluate the relationship between iron deficiency anaemia and febrile convulsions. The objective of this study was to study the role of iron deficiency as a risk factor for febrile seizures. 70 cases and 70 controls were included in the study. Cases were children of age group 6 months to 6 years presenting with febrile seizures. Controls were children of same age group presenting with febrile illness but without any seizures. A detailed history and clinical examination done in both cases and controls matched for age and sex and blood investigations were done to diagnose iron deficiency anaemia. In all children hemoglobin (Hb) level, mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), red cell distribution width (RDW) and plasma ferritin (PF) were determined and the data collected were analyzed statistically. Results: The mean PF was significantly lower in cases compared to controls \((p=0.001)\) and RDW was significantly higher in cases compared to controls \((p=0.001)\). The mean Hb%, MCV were lower in cases compared to controls. Conclusion: Iron deficiency is a significant risk factor for febrile seizures in children of age group six months to six years. Early detection and timely correction of iron deficiency may be helpful for prevention of febrile seizures in children.

KEYWORDS: Febrile seizures, iron deficiency anaemia, children.
from the study. A control group of 70 children was selected from among children hospitalized for a febrile illness (such as upper and lower respiratory tract infections and gastroenteritis) but without seizures. Controls were group matched to cases on age and sex. An informed consent was obtained from parents or the guardian. Demographic data, seizure details, nature of febrile illness, the family history of epilepsy/febrile seizures, temperature at admission and nutritional status were recorded. Blood samples were collected from all participants for measurement of haemoglobin (Hb), mean corpuscular volume (MCV), mean corpuscular haemoglobin (MCH), red cell distribution width (RDW) and serum ferritin was done.

Iron deficiency anaemia was defined as Hb <11g/dl, MCV <70 fl, MCH <27 pg, RDW >15%, serum ferritin <12 ng/ml (WHO). In presence of fever, a higher cut-off value of serum ferritin (25-50ng/ml) was considered. Cases and controls were compared with respect to blood indices and serum ferritin. Chi-square, ANOVA, unpaired t-tests were used for statistical analysis.

RESULTS
70 cases (40 male, 30 female) and 70 controls (40 male, 30 female) were enrolled. The mean ages of children in the febrile seizure and control groups were 1.7±1.2 and 1.8±1.5 year respectively. Respiratory tract infections were the most common cause of fever in the study followed by GIT infections. In this study we observed significantly low serum ferritin and significantly higher RDW in febrile seizure cases compared to controls.

DISCUSSION
Numerous studies have addressed the association between IDA and febrile seizure in children. The results, however, have been controversial and even primary researches with high number of cases have failed to provide unequivocal results. We observed significantly low serum ferritin levels in children with febrile seizures than in controls. Similar results were observed by Piscacme, et al.[15] But in contrast with these studies Mansourieltal reported mean ferritin was higher in the convulsive group with no statistically significant difference.[16] Kobrinsky et al deduced that iron deficiency might have a protective effect on febrile convulsion.[17]

Iron has been found to act as a cofactor in a number of enzymatic reactions at the cellular level and effects neurotransmitter production, hormone function and DNA replication. Deficiency of iron, therefore, results in disruption of normal cell and organ function.

Iron deficiency is associated with neurological problems in young children, including developmental delay, stroke and breath-holding spells. Screening for IDA should be considered in children with febrile seizures. Fever can worsen the negative effect of anaemia or for iron deficiency on the brain and a seizure can occur as a consequence. Alternatively, anaemia can be associated with the severity of a febrile illness and more severe cases could be more likely to get seizures.[17] Iron deficiency anaemia may reduce the seizure threshold in the infancy and childhood. Low PF level is associated with and may play a role in febrile seizures. The study has some limitations. Serum ferritin, a nonspecific acute phase reactant can rise in any inflammatory conditions, although both cases and controls were having fever at the time of enrollment. Although serum ferritin levels rise in
inflammatory conditions, MCV and RDW are not affected by acute infection.\[18\]

**CONCLUSION**
Early detection and timely correction of iron deficiency may be helpful for prevention of febrile seizures in children.
